## 1. Introduction

❑ **Infrared (IR) optical communication is a good candidate for indoor wireless communications:**

- ➔ **large bandwidth available**
- ➔ **confined to the room where they are operated: advantage for secure communications**
- ➔ **less influence on the human body than RF technologies**

❑ **We are involved in the Aircraft Light Communication (ALC) Cleansky2 H2020 project:**

- ➔ **Goal: design of a secured and performant wireless connection based on light (LiFi) for Electronic Flight Bag (EFB), headset and other pilot connected devices.**
- ➔ **Need for a flexible IR transceiver to help for the design of efficient transmission schemes**

**Software Defined Radio provides great flexibility for evaluating different optical wireless schemes. We therefore decided to design infrared optical front-ends for Ettus USRP radios.**

## 2. Design of 10MHz IR frontends for USRP radios

### Design choices

- ❑ A transmission bandwidth of 10MHz
- ❑ An IR link works in baseband with 0Hz (LED and Photodiode perform up/down conversion to the IR wavelength)
- ➔ LFTX and LFRX daughterboards cover these needs

- ➔ 0-30MHz bandwidth
- ➔ 83€
- ➔ An USRP N210 can be fitted by 1 LFTX and 1 LFRX (full duplex)

### The transmitter

- An infrared LED is current-driven

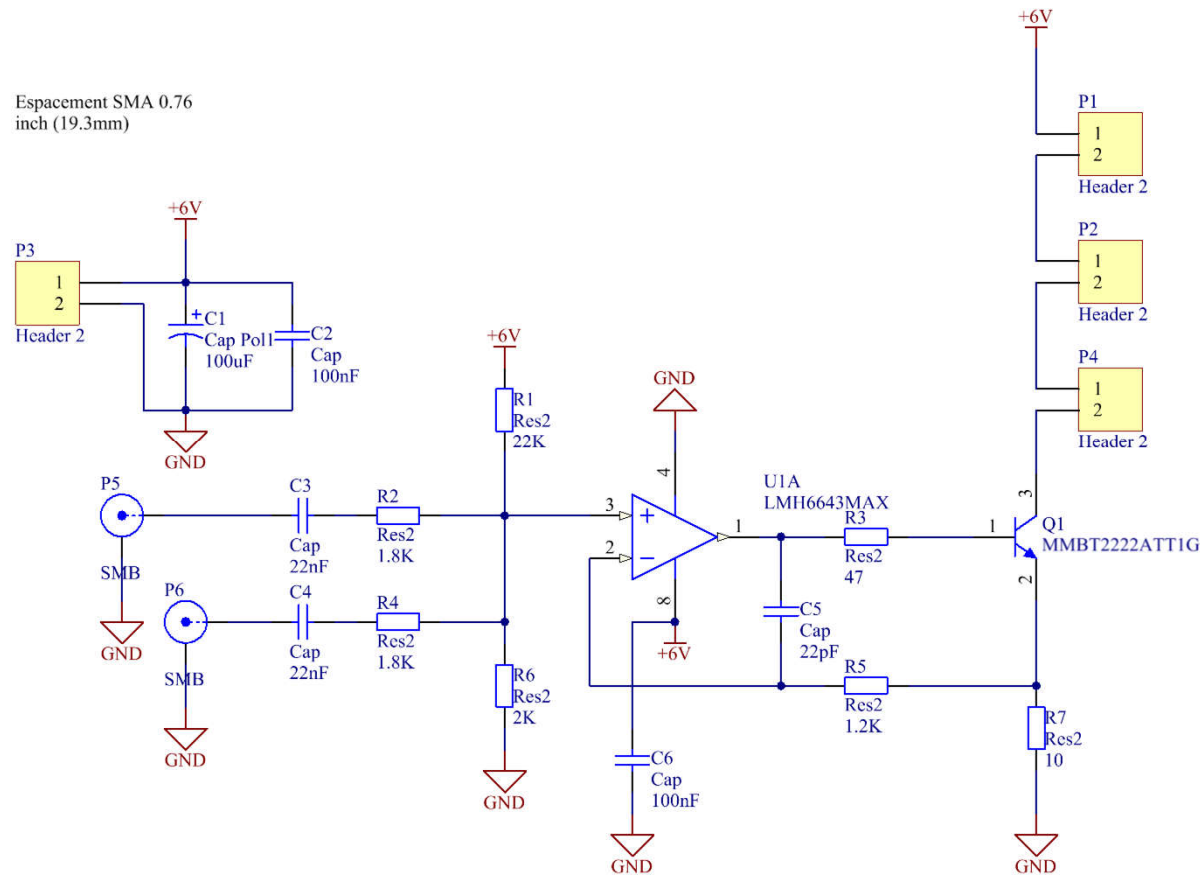

- LFTX voltage output (-1/+1V) has to be converted to 0-100mA
- Classical voltage to current converter structure with an high speed, high current operational amplifier (op amp)
- Only 6V output from USRP is able to source this current.
- An IR LED has a forward voltage of 1.7V thus we can connect up to 3 LEDs in series

## 2. Design of 10MHz IR frontends for USRP radios

### The transmitter

#### □ Schematic and designed board

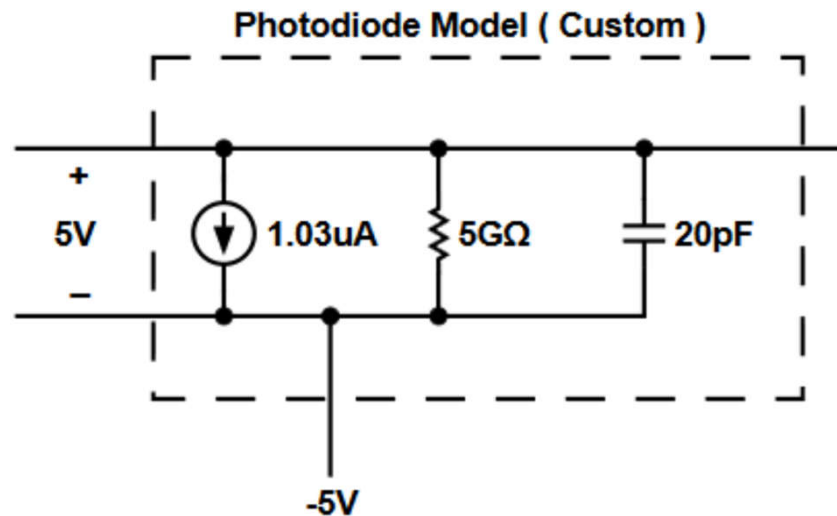

## 2. Design of 10MHz IR frontends for USRP radios

### The receiver

- A PIN photodiode is used

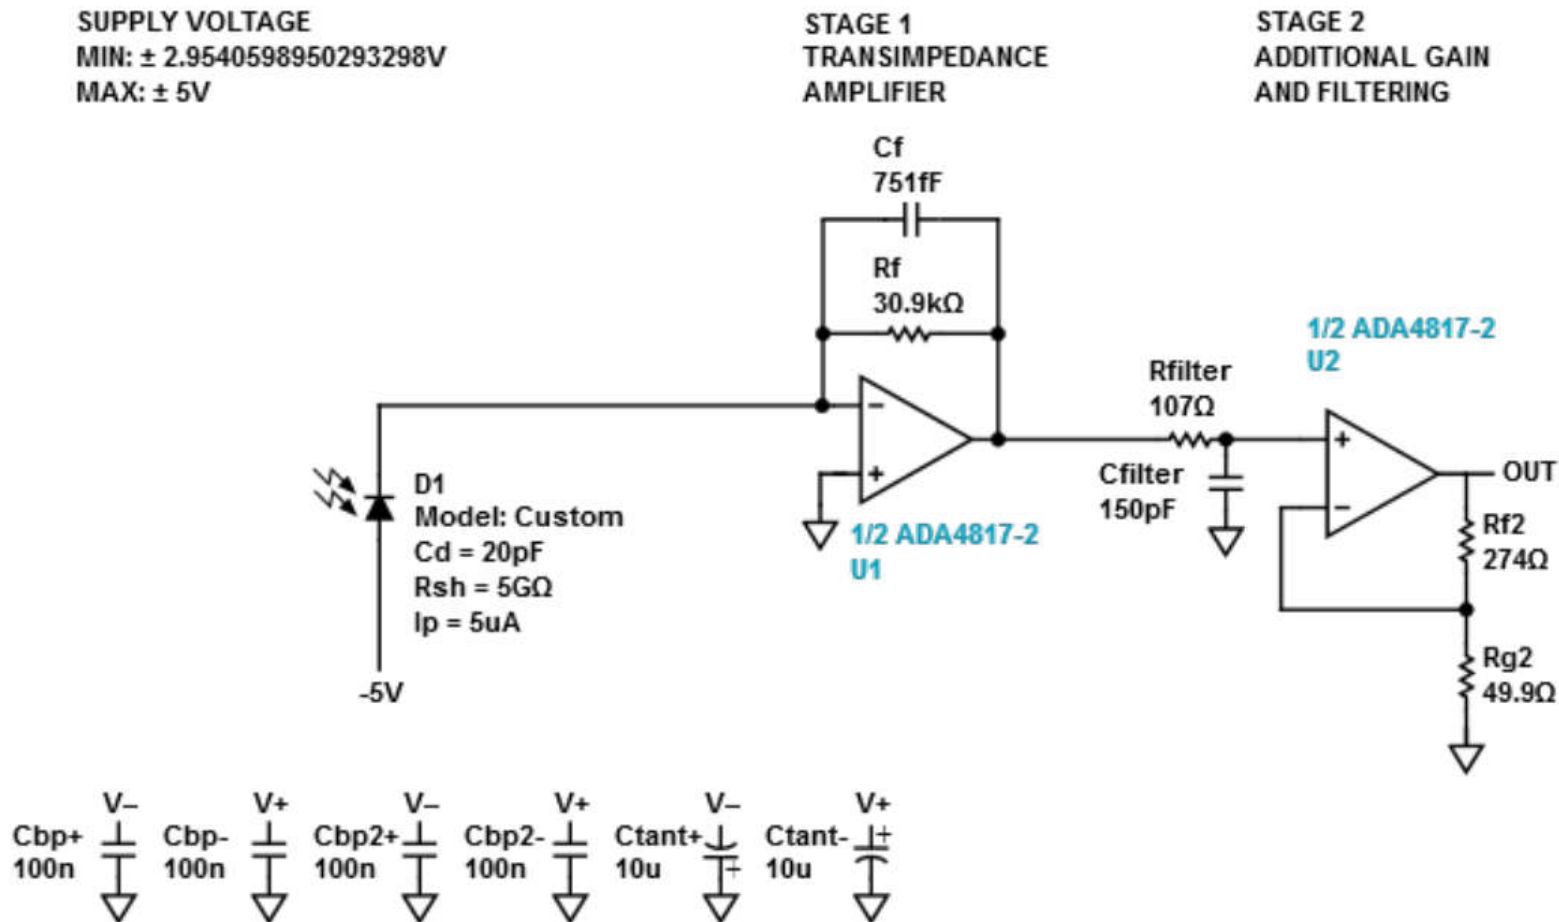

- Converts light energy into a current
- A very low current ( $10\mu\text{A}$ ) has to be converted to voltage
- The classical circuit is built around a Transimpedance Amplifier (TIA)
- There are specific op amps for this application (expensive  $\approx 10\text{€}$ )
  - Low input bias currents (JFET preamplifiers)
  - Very high gain-product bandwidth (typically over  $1\text{GHz}$ )

## 2. Design of 10MHz IR frontends for USRP radios

### The receiver

#### □ Using Analog Devices online Wizard:

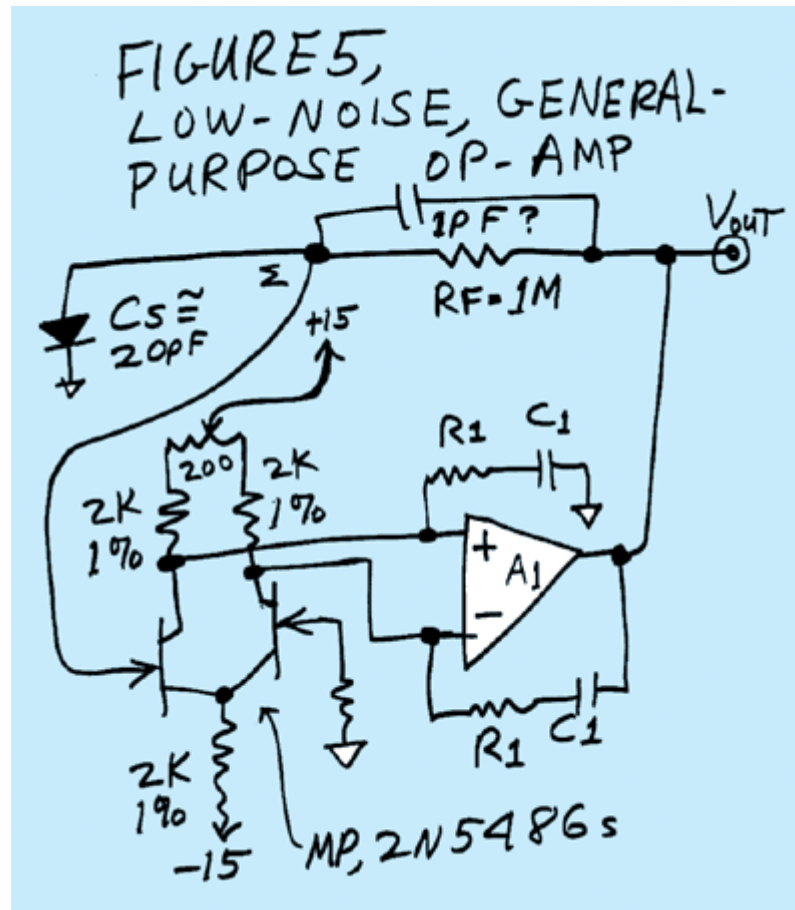

→ Extreme care has to be taken when routing the design (751fF, smd)

## 2. Design of 10MHz IR frontends for USRP radios

### The receiver

□ Reducing costs:

→ HF JFET transistor in front of a classical op amp (less than 1€)

3 - Demonstration: IR car audio  
transmission system

4 -

### 3. Demonstration: IR car audio transmission system

## IR car audio entertainment system

→ Stereo audio signal on two FM modulated carrier frequencies at 2.3MHz and 2.8MHz

### 3. Demonstration: IR car audio transmission system

## IR car audio entertainment system

- ❑ Inside the headphones (10€ on the Internet):

4 - Conclusion and future work

## 4. Conclusion and future work

- ❑ **Ettus Research offers a large range of RF daughterboards**
- ❑ **However the daughterboard interface is quite generic  
→ easy to develop a custom board**
- ❑ **This permits to enter the GNU Radio world and its huge range of librairies**
- ❑ **Our IR boards cost less than 50€.**
- ❑ **Future work: design of a configurable AGC for the IR receiver.**

---

THANK YOU!
